

Chapter 2: Data Structures

class ComplexNumber

See theory here: <http://disi.unitn.it/~montreso/sp/slides/04-struttire.pdf> (<http://disi.unitn.it/~montreso/sp/slides/04-struttire.pdf>) (First slides until class Fraction)

Let's try to define a complex number:

A **complex number** is a **number** that can be expressed in the form $a + bi$, where a and b are real **numbers** and i is the imaginary unit which satisfies the equation $i^2 = -1$. In this expression, a is the real part and b is the imaginary part of the **complex number**.

Complex number - Wikipedia
https://en.wikipedia.org/wiki/Complex_number

As the Fraction class, the ComplexNumber holds two values, in this case one for the *real* part and one for the *imaginary* one.

- Note each method takes as first import `self` argument. `self` will always be a reference to the object itself, and allows accessing its fields and methods
- `self` is not a keyword of Python, you could use any name you want for the first parameter, but it is much better to follow conventions and stick using `self` !
- Methods beginning and ending with double underscore `'__'` have often special meaning in Python: if you see such a method around, it means it is overriding some default behaviour of Python

In [2]:

```
import unittest
import math

class ComplexNumber:

    def __init__(self, real, imaginary):
        self.real = real
        self.imaginary = imaginary

    def phase(self):
        """ Returns a float which is the phase (that is, the vector angle) of the complex number

        This method is something we introduce by ourselves, according to the definition:
        https://en.wikipedia.org/wiki/Complex_number#Absolute_value_and_argument
        """
        return math.atan2(self.imaginary, self.real)

    def log(self, base):
        """ Returns another ComplexNumber which is the logarithm of this complex number

        This method is something we introduce by ourselves, according to the definition:
        (accomodated for generic base b)
        https://en.wikipedia.org/wiki/Complex_number#Natural_logarithm
        """
```

```

    """
    return ComplexNumber(math.log(self.real) / math.log(base), self.phase() / ma
th.log(base))

def __str__(self):
    return str(self.real) + " + " + str(self.imaginary) + "i"

class ComplexNumberTest(unittest.TestCase):

    """ Test cases for ComplexNumber

    Note this is a *completely* separated class from ComplexNumber and
    we declare it here just for testing purposes!
    The 'self' you see here have nothing to do with the selfs from the
    ComplexNumber methods!
    """

    def test_init(self):
        self.assertEqual(ComplexNumber(1,2).real, 1)
        self.assertEqual(ComplexNumber(1,2).imaginary, 2)

    def test_phase(self):
        """
        NOTE: we can't use assertEquals, as the result of phase() is a
        float number which may have floating point rounding errors. So it's
        necessary to use assertAlmostEqual
        As an option with the delta you can declare the precision you require.
        For more info see Python docs:
        https://docs.python.org/2/library/unittest.html#unittest.TestCase.assert
        AlmostEqual

        NOTE: assertEquals might still work on your machine but just DO NOT use i
        t
        for float numbers!!!
        """
        self.assertAlmostEqual(ComplexNumber(0.0,1.0).phase(), math.pi / 2, delta=0.
001)

    def test_str(self):
        self.assertEqual(str(ComplexNumber(1,2)), "1 + 2i")
        #self.assertEqual(str(ComplexNumber(1,0)), "1")
        #self.assertEqual(str(ComplexNumber(1.0,0)), "1.0")
        #self.assertEqual(str(ComplexNumber(0,1)), "i")
        #self.assertEqual(str(ComplexNumber(0,0)), "0")

    def test_log(self):
        c = ComplexNumber(1.0,1.0)
        l = c.log(math.e)
        self.assertAlmostEqual(l.real, 0.0, delta=0.001)
        self.assertAlmostEqual(l.imaginary, c.phase(), delta=0.001)

```

In [3]:

```

algolab.run(ComplexNumberTest)

```

```

....
-----
Ran 4 tests in 0.003s

```

OK

Once the `__init__` method is defined, we can create a `ComplexNumber` with a call like `'ComplexNumber(3,5)'`

Notice in the constructor call we *do not* pass anything as `self` parameter (after all, we are creating the object)

In [4]:

```
my_complex = ComplexNumber(3,5)
```

We can now try to use one of the methods we defined:

In [5]:

```
phase = my_complex.phase()  
print phase
```

```
1.03037682652
```

We can also pretty print the whole complex number. Internally, `print` function will look if the `ComplexNumber` has defined an `__str__` method. If so, it will pass to the method the instance `my_complex` as the first argument, which in our methods will end up in the `self` parameter:

In [6]:

```
print my_complex
```

```
3 + 5i
```

We can also call methods that require a parameter like `log(base)`. Notice that `log` function returns a `ComplexNumber`, and Python will automatically pretty print it for us.

In [7]:

```
logarithm = my_complex.log(math.e)  
print logarithm
```

```
1.09861228867 + 1.03037682652i
```

Ok, now we are ready to define our own stuff.

Complex numbers magnitude

The *absolute value* (or *modulus* or *magnitude*) of a complex number $z = x + yi$ is

$$r = |z| = \sqrt{x^2 + y^2}.$$

Implement the magnitude method, using this signature:

```
def magnitude(self):
    """ Returns a float which is the magnitude (that is, the absolute value) of the complex number

    This method is something we introduce by ourselves, according to the definition:
    https://en.wikipedia.org/wiki/Complex_number#Absolute_value_and_argument
    """
    raise Exception("TODO implement me!")
```

To test it, add this test case to ComplexNumberTest class (notice the almost in assertAlmostEqual !!!):

```
def test_magnitude(self):
    self.assertAlmostEqual(ComplexNumber(3.0,4.0).magnitude(),5, delta=0.001)
```

Complex numbers equality

Here we will try to give you a glimpse of some aspects related to Python equality, and trying to respect interfaces when overriding methods. Equality can be a nasty subject, here we will treat it in a simplified form.

Equality [\[edit\]](#)

Two complex numbers are equal **if and only if** both their real and imaginary parts are equal. In symbols:

$$z_1 = z_2 \leftrightarrow (\text{Re}(z_1) = \text{Re}(z_2) \wedge \text{Im}(z_1) = \text{Im}(z_2)).$$

- Implement equality for ComplexNumber more or less as it was done for Fraction

Use this method signature:

```
def __eq__(self, other):
```

and use this simple test case to check for equality:

```
def test_integer_equality(self):
    """
        Note all other tests depend on this test !

        We want also to test the constructor, so in c we set stuff by hand
    """
    c = ComplexNumber(0,0)
    c.real = 1
    c.imaginary = 2
    self.assertEqual(c, ComplexNumber(1,2))
```

- Beware 'equality' is tricky in Python for float numbers! Rule of thumb: when overriding __eq__, use 'dumb' equality, two things are the same only if their parts are literally equal
- If instead you need to determine if two objects are similar, define other 'closeness' functions.
- (Non mandatory read) if you are interested in the gory details of equality, see
 - [How to Override comparison operators in Python \(http://jcalderone.livejournal.com/32837.html\)](http://jcalderone.livejournal.com/32837.html)
 - [Messing with hashing \(http://www.asmeurer.com/blog/posts/what-happens-when-you-mess-with-hashing-in-python/\)](http://www.asmeurer.com/blog/posts/what-happens-when-you-mess-with-hashing-in-python/)

Complex numbers isclose

Complex numbers can be represented as vectors, so intuitively we can determine if a complex number is close to another by checking that the distance between its vector tip and the the other tip is less than a given delta. There are more precise ways to calculate it, but here we prefer keeping the example simple.

Given two complex numbers

$$z_1 = a + bi$$

and

$$z_2 = c + di$$

We can consider them as close if they satisfy this condition:

$$\sqrt{(a-c)^2 + (b-d)^2} < \delta$$

- Implement the method, adding it to ComplexNumber class:

```
def isclose(self, c, delta):  
    """ Returns True if the complex number is within a delta distance from  
    complex number c.  
    """  
    raise Exception("TODO Implement me!")
```

and add this test case to ComplexNumberTest class:

```
def test_isclose(self):  
    """ Notice we use `assertTrue` because we expect `isclose` to return  
    a `bool` value, and  
    we also test a case where we expect `False`  
    """  
    self.assertTrue(ComplexNumber(1.0,1.0).isclose(ComplexNumber(1.0,1.1)  
    , 0.2))  
    self.assertFalse(ComplexNumber(1.0,1.0).isclose(ComplexNumber(10.0,10  
    .0), 0.2))
```

REMEMBER: Equality with `__eq__` and closeness functions like `isclose` are very different things. Equality should check if two objects have the same memory address or, alternatively, if they contain the same things, while closeness functions should check if two objects are similar. You should never use functions like `isclose` inside `__eq__` methods, unless you really know what you're doing.

Complex numbers addition

Complex numbers are **added** by separately adding the real and imaginary parts of the summands.

That is to say:

$$(a + bi) + (c + di) = (a + c) + (b + d)i.$$

Similarly, **subtraction** is defined by

$$(a + bi) - (c + di) = (a - c) + (b - d)i.$$

- a and c correspond to real, b and d correspond to imaginary
- implement addition for ComplexNumber more or less as it was done for Fraction in theory slides
- write some tests as well!

Use this definition:

```
def __add__(self, other):  
    raise Exception("TODO implement me!")
```

And add this to the ComplexNumberTest class:

```
def test_add_zero(self):  
    self.assertEqual(ComplexNumber(1,2) + ComplexNumber(0,0), ComplexNum  
ber(1,2));  
  
    def test_add_numbers(self):  
        self.assertEqual(ComplexNumber(1,2) + ComplexNumber(3,4), ComplexNum  
ber(4,6));
```

Adding a scalar

We defined addition among ComplexNumbers, but what about addition among a ComplexNumber and an int or a float?

Will this work?

```
ComplexNumber(3,4) + 5
```

What about this?

```
ComplexNumber(3,4) + 5.0
```

Try to add the following method to your class, and check if it does work with the scalar:

In [9]:

```
def __add__(self, other):  
    # checks other object is instance of the class ComplexNumber  
    if isinstance(other, ComplexNumber):  
        return ComplexNumber(self.real + other.real, self.imaginary + other.imagi  
nary)  
  
    # else checks the basic type of other is int or float  
    elif type(other) is int or type(other) is float:  
        return ComplexNumber(self.real + other, self.imaginary)  
  
    # other is of some type we don't know how to process.  
    # In this case the Python specs say we MUST return 'NotImplemented'  
    else:  
        return NotImplemented
```

Hopefully now you have a better add. But what about this? Will this work?

```
5 + ComplexNumber(3,4)
```

Answer: it won't, Python needs further instructions. Usually Python tries to see if the class of the object on left of the expression defines addition for operands *to the right* of it. In this case on the left we have a float number, and float numbers don't define any way to deal to the right with your very own ComplexNumber class. So as a last resort Python tries to see if your ComplexNumber class has defined also a way to deal with operands *to the left* of the ComplexNumber, by looking for the method `__radd__`, which means *reverse addition*. Here we implement it :

```
def __radd__(self, other):
    """ Returns the result of expressions like    other + self    """
    if (type(other) is int or type(other) is float):
        return ComplexNumber(self.real + other, self.imaginary)
    else:
        return NotImplemented
```

To check it is working and everything is in order for addition, add these test cases:

```
def test_add_zero(self):
    self.assertEqual(ComplexNumber(1,2) + ComplexNumber(0,0), ComplexNumber(1,2));

    def test_add_numbers(self):
        self.assertEqual(ComplexNumber(1,2) + ComplexNumber(3,4), ComplexNumber(4,6));

    def test_add_scalar_right(self):
        self.assertEqual(ComplexNumber(1,2) + 3, ComplexNumber(4,2));

    def test_add_scalar_left(self):
        self.assertEqual(3 + ComplexNumber(1,2), ComplexNumber(4,2));

    def test_add_negative(self):
        self.assertEqual(ComplexNumber(-1,0) + ComplexNumber(0,-1), ComplexNumber(-1,-1));
```

Complex numbers multiplication

Multiplication and division [\[edit\]](#)

The multiplication of two complex numbers is defined by the following formula:

$$(a + bi)(c + di) = (ac - bd) + (bc + ad)i.$$

In particular, the [square](#) of the imaginary unit is -1 :

$$i^2 = i \times i = -1.$$

- Implement multiplication for `ComplexNumber`, taking inspiration from previous `__add__` implementation
- Can you extend multiplication to work with scalars (both left and right) as well?

To implement `__mul__`, copy this definition into `ComplexNumber` class:

```
def __mul__(self, other):  
    raise Exception("TODO Implement me!")
```

and add test cases to `ComplexNumberTest` class:

```
def test_mul_by_zero(self):  
    self.assertEqual(ComplexNumber(0,0) * ComplexNumber(1,2), ComplexNumber(0,0));  
  
    def test_mul_just_real(self):  
        self.assertEqual(ComplexNumber(1,0) * ComplexNumber(2,0), ComplexNumber(2,0));  
  
    def test_mul_just_imaginary(self):  
        self.assertEqual(ComplexNumber(0,1) * ComplexNumber(0,2), ComplexNumber(-2,0));  
  
    def test_mul_scalar_right(self):  
        self.assertEqual(ComplexNumber(1,2) * 3, ComplexNumber(3,6));  
  
    def test_mul_scalar_left(self):  
        self.assertEqual(3 * ComplexNumber(1,2), ComplexNumber(3,6));
```

Stack

Stack theory

Stack exercises

On slide 46 of [theory \(http://disi.unitn.it/~montreso/sp/slides/04-strutture.pdf\)](http://disi.unitn.it/~montreso/sp/slides/04-strutture.pdf) (Slide 46) there is the pseudo code for a version of stack we will call CappedStack:

STACK		
ITEM[] <i>A</i>	% Elements	ITEM peek()
int <i>size</i>	% Current size	if <i>size</i> > 0 then
int <i>cap</i>	% Maximum size	return <i>A[size]</i>
STACK Stack(int <i>dim</i>)		ITEM pop()
STACK <i>t</i> ← new STACK		if <i>size</i> > 0 then
<i>t.A</i> ← new int[1... <i>dim</i>]		ITEM <i>t</i> ← <i>A[size]</i>
<i>t.cap</i> ← <i>dim</i>		<i>size</i> ← <i>size</i> - 1
<i>t.size</i> ← 0		return <i>t</i>
return <i>t</i>		
boolean isEmpty()		push(ITEM <i>v</i>)
return <i>size</i> = 0		if <i>size</i> < <i>cap</i> then
int size()		<i>size</i> ← <i>size</i> + 1
return <i>size</i>		<i>A[size]</i> ← <i>v</i>

A capped stack has a limit called *cap* over which elements are discarded:

- Copy the [following skeleton and unit tests](#), and then implement the pseudo code
- Name internal variables that you don't want to expose to class users by prepending them with one underscore '_', like `_elements` or `_cap`.
 - The underscore is just a convention, class users will still be able to get internal variables by accessing them with field accessors like `mystack._elements`.
 - If users manipulate private fields and complain something is not working, you can tell them it's their fault!
- This time, we will try to write a little more robust code. In general, when implementing pseudocode you might need to think more about boundary cases. In this case, we add the additional constraint that if you pass to the stack a negative or zero *cap*, your class initialization is expected to fail and raise an `AssertionError`. Such error can be raised by commands like `assert my_condition` where `my_condition` is `False`
- For easier inspection of the stack, implement also an `__str__` method so that calls to `print` show text like `CappedStack: cap=4 elements=['a', 'b']`

IMPORTANT: The psudo code uses indexes to keep track the stack size. Since you are providing an actual implementation in Python, you can exploit any Python feature you deem correct to implement the data structure, and even depart a bit from the literal pseudo code. For example, internally you could represent the data as a list, and use its own methods to grow it.

QUESTION: If we already have Python lists that can more or less do the job of the stack, why do we need to wrap them inside a Stack? Can't we just give our users a Python list?

QUESTION: When would you *not* use a Python list to hold the data in the stack?

Notice that:

- We tried to use more pythonic names (<https://www.python.org/dev/peps/pep-0008/#id45>) for methods, so for example `isEmpty` was renamed to `is_empty`
- In this case, when this stack reaches cap size, successive push requests silently exit without raising errors. Other implementations might raise an error and stop excecution when trying to push over on already filled stack.
- In this case, when this stack is required to pop or peek, if it is empty the functions will not return anything. During the Python translation, we might not return anything as well and relying on Python implicitly returning `None`.
- `pop` will both modify the stack *and* return a value

CappedStack Code Skeleton

In [11]:

```
import unittest

class CappedStack:

    def __init__(self, cap):
        """ Creates a CappedStack capped at cap. Cap must be > 0, otherwise an AssertionError is thrown """
        raise Exception("TODO Implement me!")

    def size(self):
        raise Exception("TODO Implement me!")

    def is_empty(self):
        raise Exception("TODO Implement me!")

    def pop(self):
        raise Exception("TODO Implement me!")

    def peek(self):
        raise Exception("TODO Implement me!")

    def push(self, item):
        raise Exception("TODO Implement me!")

    def cap(self):
        """ Returns the cap of the stack """
```

```
raise Exception("TODO Implement me!")
```

```
class CappedStackTest(unittest.TestCase):
```

```
    """ Test cases for CappedStackTest
```

```
        Note this is a *completely* separated class from CappedStack and
        we declare it here just for testing purposes!
        The 'self' you see here have nothing to do with the selfs from the
        CappedStack methods!
    """
```

```
def test_init_wrong_cap(self):
```

```
    """
```

```
        We use the special construct 'self.assertRaises(AssertionError)' to state
        we are expecting the calls to CappedStack(0) and CappedStack(-1) to raise
        an AssertionError.
    """
```

```
with self.assertRaises(AssertionError):
```

```
    CappedStack(0)
```

```
with self.assertRaises(AssertionError):
```

```
    CappedStack(-1)
```

```
def test_cap(self):
```

```
    self.assertEqual(CappedStack(1).cap(), 1)
```

```
    self.assertEqual(CappedStack(2).cap(), 2)
```

```
def test_size(self):
```

```
    s = CappedStack(5)
```

```
    self.assertEqual(s.size(), 0)
```

```
    s.push("a")
```

```
    self.assertEqual(s.size(), 1)
```

```
    s.pop()
```

```
    self.assertEqual(s.size(), 0)
```

```
def test_is_empty(self):
```

```
    s = CappedStack(5)
```

```
    self.assertTrue(s.is_empty())
```

```
    s.push("a")
```

```
    self.assertFalse(s.is_empty())
```

```
def test_pop(self):
```

```
    s = CappedStack(5)
```

```
    self.assertEqual(s.pop(), None)
```

```
    s.push("a")
```

```
    self.assertEqual(s.pop(), "a")
```

```
    self.assertEqual(s.pop(), None)
```

```
def test_peek(self):
```

```
    s = CappedStack(5)
```

```
    self.assertEqual(s.peak(), None)
```

```
    s.push("a")
```

```
    self.assertEqual(s.peak(), "a")
```

```
    self.assertEqual(s.peak(), "a") # testing peek is not changing the stack
```

```
    self.assertEqual(s.size(), 1)
```

```
def test_push(self):
```

```
    s = CappedStack(2)
```

```
    self.assertEqual(s.size(), 0)
```

```
    s.push("a")
```

```

s.push("a")
self.assertEqual(s.size(), 1)
s.push("b")
self.assertEqual(s.size(), 2)
self.assertEqual(s.peek(), "b")
s.push("c") # capped, pushing should do nothing now!
self.assertEqual(s.size(), 2)
self.assertEqual(s.peek(), "b")

```

```

def test_str(self):
    s = CappedStack(4)
    s.push("a")
    s.push("b")
    print s

```

UnorderedList

UnorderedList Theory

An UnorderedList for us is a linked list starting with a pointer called *head* that points to the first Node (if the list is empty the pointer points to None). Think of the list as a chain where each Node can contain some data retrievable with `Node.get_data()` method and you can access one Node at a time by calling the method `Node.get_next()` on each node.

- See [theory slides \(http://disi.unitn.it/~montreso/sp/slides/04-strutture.pdf\)](http://disi.unitn.it/~montreso/sp/slides/04-strutture.pdf) from slide 25 (Monodirectional list)
- See [UnorderedList Abstract Data Type \(http://interactivepython.org/runestone/static/pythonds/BasicDS/TheUnorderedListAbstractDataType.html\)](http://interactivepython.org/runestone/static/pythonds/BasicDS/TheUnorderedListAbstractDataType.html) on the book
- See [Implementing UnorderedListLinkedLists \(http://interactivepython.org/runestone/static/pythonds/BasicDS/ImplementinganUnorderedListLinkedLists.html\)](http://interactivepython.org/runestone/static/pythonds/BasicDS/ImplementinganUnorderedListLinkedLists.html) on the book

UnorderedList Exercises

1) Understand the problem

Copy [the following skeleton and unit tests](#), and then implement the missing methods, in the order they are presented in the skeleton.

- This time there is not much pseudo or Python code to find around, you should rely solely on theory from the slides and book, method definitions and your intuition
- Pay close attention to the comments below each method definition, especially for boundary cases

COMMANDMENT: You shall also draw lists on paper, helps a lot avoiding mistakes

WARNING: Do *not* use a Python list to hold data inside the data structure. Differently from the CappedStack exercise, here you can only use Node class. Each Node in the `_data` field can hold only one element which is provided by the user of the class, and we don't care about the type of the value the user gives us (so it can be an `int`, a `float`, a `string`, or even a Python list !)

WARNING: NEVER EVER WRITE code like this: `self = something`

Instead, assign values to *fields* of `self`, like `self._head = something`

WARNING: if there isn't the word "*Return*" in a method comment, then most probably that method does not return anything!

WARNING: Methods of the class `UnorderedList` are supposed to *never* return instances of `Node`. If you see them returned in the tests, then you are making some mistake. Users of `UnorderedList` are should only be able to get access to items inside the `Node` data fields.

Notice that there are a few differences with the book:

- We don't assume the list has all different values
- We used more pythonic names (<https://www.python.org/dev/peps/pep-0008/#id45>) for properties and methods, so for example private attribute `Node.data` was renamed to `Node._data` and accessor method `Node.getData()` was renamed to `Node.get_data()`. There are nicer ways to handle these kind of getters/setters pairs called 'properties' but we won't address them here.
- In boundary cases like removing a non-existing element we prefer to raise an exception with the command

```
raise Exception("Some error occurred!")
```

In general, this is the behaviour you also find in regular Python lists.

2) Save a copy of your work

You already wrote a lot of code, and you don't want to lose it, right? Since we are going to make many modifications, when you reach a point when the code does something useful, it is good practice to save a copy of what you have done somewhere, so if you later screw up something, you can always restore the copy of the work

- Add also somewhere in the copy (in a comment at the top of the `.py` file or in a separate `README.txt` file) the version (like `1.0`), the date, and a description of the main features (for example "Simple linked list, not particularly performant").
- Backing up the work is a form of the so-called *versioning*: there are much better ways to do it (like using [git](https://git-scm.com) (<https://git-scm.com>)) but we don't address them here.

3) Faster size()

Implement a `size()` method that works in $O(1)$. To make this work without going through the whole list each time, we will need a new `_size` field that keeps track of the size. When the list is mutated with methods like `add`, `append`, etc you will also need to update the `_size` field accordingly. Proceed like this:

3.1) add a new field `_size` in the class constructor and initialize it to zero

3.2) modify the `size()` method to just return the `_size` field.

3.3) The data structure starts to be complex, and we need better testing. If you look at the tests, very often there are lines of code like `self.assertEqual(ul.to_python(), ['a', 'b'])` in the `test_add` method:

```
def test_add(self):
    ul = UnorderedList()
    self.myAssert(ul, [])
    ul.add('b')
    self.assertEqual(ul.to_python(), ['b'])
    ul.add('a')
    self.assertEqual(ul.to_python(), ['a', 'b'])
```

Last line checks our unordered list `ul` contains a sequence of linked nodes that once transformed to a python list actually equals `['a', 'b']`. Since in the new implementation we are going to mutate `_size` field a lot, it could be smart to also check that `ul.size()` equals `len(["a", "b"])`. Repeating this check in every test method could be quite verbose. Instead, we can do a smarter thing, and develop in the `UnorderedListTest` class a new assertion method on our own:

3.3.1) Add this method to `UnorderedListTest` class:

```
def myAssert(self, unordered_list, python_list):
    """ Checks provided unordered_list can be represented as the given python_list. Since v2.
    """
    self.assertEqual(unordered_list.to_python(), python_list)
    # check this new invariant about the size
    self.assertEqual(unordered_list.size(), len(python_list))
```

WARNING: method myAssert must *not* be with test_, otherwise unittest will run it as a test!

3.3.2) Now, how to use this powerful new myAssert method? In the test class, just replace every occurrence of

```
self.assertEqual(ul.to_python(), ['a', 'b'])
```

into calls like this:

```
self.myAssert(ul, ['a', 'b'])
```

WARNING: Notice the `.to_python()` after `ul` is gone.

3.4) Actually update `_size` in the various methods where data is mutated, like `add`, `insert`, etc.

3.5) Run the tests and hope for the best ;-)

4) Faster append()

We are now better equipped to make further improvements. Once you're done implementing the above and made sure everything works, you can implement an append method that works in $O(1)$ by adding an additional pointer in the data structure that always point at the last node. To further exploit the pointer, you can also add a fast `last(self)` method that returns the last value in the list. Proceed like this:

4.1) Save a copy of your work somewhere, putting version (2.0), date, and comments on the improvements.

4.2) Add an additional pointer called `_last` in the constructor.

4.3) Copy this method into the class. Just copy it, don't implement it for now.

```
def last(self):
    """ Returns the last element in the list, in  $O(1)$ .

        If list is empty, raises an Exception. Since v2.
    """
    raise Exception("TODO implement me!")
```

4.4) Let's do some so-called *test driven development*, that is, first we write the tests, then we write the implementation.

WARNING: During the exam you *will* be asked to write tests, so don't skip writing them now !!

4.4.1) Implement a test for `last()` method, by adding this to `UnorderedListTest` class:

```
def test_last(self):
    raise Exception("TODO IMPLEMENT ME !")
```

In the method, create a list and add elements using only calls to `add` method and checks using the `myAssert` method. When done, ask your instructor if the test is correct (or look at the proposed solution at the bottom of the worksheet), it is important you get it right otherwise you won't be able to properly test your code.

4.4.2) You already have a test for the `append()` method, but, how can you be sure the `_last` pointer is updated correctly throughout the code? When you implemented the fast `size()` method you wrote some invariant in the `myAssert` method. We can do the same this time, too. Find the invariant and add the corresponding check to the

myAssert method. When done, ask your instructor if the invariant is correct (or look at the proposed solution at the bottom of the worksheet): it is important you get it right otherwise you won't be able to properly test your code.

4.5) Update the methods that mutate the data structure (add, insert, remove ...) so they keep `_last` pointed to last element. If the list is empty, `_last` will point to None. Taking particular care of corner cases such as empty list and one element list.

4.6) Cross your fingers and run the tests!

5) Go bidirectional

Our list so far has links that allow us to traverse it fast in one direction. But what if we want fast traversal in the reverse direction, from last to first element? What if we want a `pop()` that works in $O(1)$? To speed up these operations we could add backward links to each Node. Proceed in the following way:

5.1) Save your work

Once you're done with previous points, save the version you have somewhere adding comments about the improvements done so far, the version number (like 2.0) and the date. Then start working on a new copy.

5.2) Node backlinks

In Node class, add backlinks by adding the attribute `_prev` and methods `get_prev(self)` and `set_prev(self, pointer)`.

5.3) Better `__str__`

Improve `__str__` method so it shows presence or absence of links, along with the size of the list. `next` pointers presence must be represented with `>` character, absence with `*` character. They must be put after the item representation. `prev` pointers presence must be represented with `<` character, absence with `*` character. They must be put before the item representation.

For example, for the list `['a','b','c']`, you would have the following representation:

```
UnorderedList(size=3):*a><b><c*
```

As a special case for empty list you should print the following:

```
UnorderedList(size=0):[]
```

Other examples of proper lists, with 3, 2, and 1 element can be:

```
UnorderedList(size=3):*a><b><c*
UnorderedList(size=2):*a><b*
UnorderedList(size=1):*a*
```

This new `__str__` method should help you to spot broken lists like the following, were some pointers are not correct:

```
Broken list, all prev pointers are missing:
UnorderedList(size=3):*a>*b>*c*
```

```
Broken list, size = 3 but shows only one element with next pointer set to None:
UnorderedList(size=3):*a*
```

```
Broken list, first backward pointer points to something other than None
UnorderedList(size=3):<a><b><c*
```

5.4) Modify add()

Update the `UnorderedList` `add` method to take into account you now have backlinks. Take particular care for the boundary cases when the list is empty, has one element, or for nodes at the head and at the tail of the list.

5.5) Add to `_python_reversed()`

Implement to_python_reversed method with a linear scan by using the newly added backlinks:

```
def to_python_reversed(self):  
    """ Returns a regular Python list with the elements in reverse order,  
        from last to first. Since v3. """  
    raise Exception("TODO implement me")
```

Add also this test, and make sure it pass:

```
def test_to_python_reversed(self):  
    ul = UnorderedList()  
    ul.add('c')  
    ul.add('b')  
    ul.add('a')  
    pr = ul.to_python()  
    pr.reverse() # we are reversing pr with Python's 'reverse()' method  
    self.assertEqual(pr, ul.to_python_reversed())
```

5.6) Add invariant

By using the method to_python_reversed(), add a new invariant to the myAssert method. If implemented correctly, this will surely spot a lot of possible errors in the code.

5.7) Modify other methods

Modify all other methods that mutate the data structure (insert, remove, etc) so that they update the backward links properly.

5.8) Run the tests

If you wrote meaningful tests and all pass, congrats!

UnorderedList Code Skeleton

In [16]:

```
import unittest  
  
class Node:  
    def __init__(self, initdata):  
        self._data = initdata  
        self._next = None
